(54) Title: APPARATUS FOR CHECKING DIMENSIONAL AND GEOMETRICAL FEATURES OF PINS

(57) Abstract: An apparatus for checking the diameter and the roundness of pins, for example crankpins and main journals of a crankshaft rotating about its main axis of rotation (8), includes a measuring device, coupled to a Vee-shaped reference device (20) and including a feeler (17) axially movable along the bisecting line of the Vee, or a direction slightly sloping with respect to it, and a movable support device for the reference Vee. The support device includes a support element (5) and a coupling mechanism that carries the reference Vee (20). The coupling mechanism includes, for example, two support sections (e.g. parallelogram structures) in series and enables plain translation displacements of the reference Vee. While checking an orbitally rotating crankpin, the Vee-shaped device maintains proper contact with the surface of the pin by virtue of the force of gravity, and the angular arrangement of the direction along which the feeler (17) moves remains substantially unchanged.

WO 02/070195 A1

**«APPARATUS FOR CHECKING DIMENSIONAL AND GEOMETRICAL  
FEATURES OF PINS»**

5

Technical Field

The present invention relates to an apparatus for checking dimensional and geometrical features of a pin, rotating about a geometrical axis of rotation, with a Vee-shaped device that defines rest and reference surfaces adapted for cooperating with the pin to be checked, a measuring device, coupled to the Vee-shaped device and including a feeler for contacting the surface of the pin to be checked and performing linear displacements along a measurement direction laying between the rest and reference surfaces of the Vee-shaped reference device, and a support device for supporting the Vee-shaped device and the measuring device, the support device including a stationary support element, and a coupling mechanism with coupling elements coupled in a movable way to the stationary support element and carrying the Vee-shaped device.

Background Art

25

Apparatuses with these characteristics, for example for the checking of a crankpin diameter of a crankshaft rotating with orbital motion about a geometrical axis in the course of the machining in a grinding machine, are disclosed in international patent application published with No. WO-A-9712724, filed by the same applicant of the present application.

In particular, according to the embodiments shown and described in the above mentioned international patent application, the apparatuses have Vee-shaped reference devices that rest on the crankpin to be checked, and maintain correct cooperation with the surface of the

35

- 2 -

crankpin substantially owing to the force of gravity.

The embodiments disclosed in the above-mentioned patent application guarantee excellent metrological results and small forces of inertia, and the standards of performance  
5 of the apparatuses with these characteristics, manufactured by the applicant of the present patent application, confirm the remarkable quality and reliability of the applications. Furthermore, these known apparatuses can be utilized for carrying out roundness checkings of the cylindrical  
10 surfaces of the pins, while the crankshaft is assembled and rotates on the grinding machine.

International patent application published with No. WO-A-0166306, filed by the same applicant of the present patent application, relates to an apparatus and a method for  
15 checking the roundness of crankpins in orbital rotation on a grinding machine. This international patent application describes the detecting of diameter dimensions of the crankpin, at predetermined angular positions of the crankshaft rotation, by means of a gauging head including a  
20 feeler and Vee-shaped reference surfaces that rest on the piece and a transducer that detects displacements of the feeler along a direction of measurement coincident with the bisecting line of the Vee or slightly inclined with respect to it.

25 The detected dimensions are processed, for both compensating alterations due to the particular type of head used (modulation of the shape errors of the checked surface that is in contact with the reference Vee) and carrying out other compensations for keeping into account the position  
30 taken by the head on the surface of the crankpin, more specifically the angularly arranged position of the point of contact of the feeler with respect to a known reference position, that depends on the relative arrangement between the support element and the crankshaft and on the  
35 characteristics and consequent configurations taken by the support device carrying the head. Figures 1a and 1b show, in an extremely simplified form, some parts of a known

- 3 -

apparatus, coupled to the grinding-wheel slide of a grinding machine, in the course of the checkings of a cylindrical crankpin. In order to emphasize how the angular arrangement of the measurement direction **D** defined by  
5 feeler **T** depends on the mutual position between piece to be checked and coupling area of the apparatus, figures 1a and 1b show two different checking conditions. In the first condition (figure 1a) the apparatus checks the pin while the latter is in contact with the grinding wheel, in the  
10 second condition (figure 1b), the checking takes place while the grinding-wheel slide is retracted with respect to the piece. It is also necessary to realize that in the course of the checking of a pin in orbital motion (for example a crankpin), variations in the configuration of the  
15 support device cause consequent variations in the angular arrangement of the feeler.

The method according to international patent application WO-A-0166306 enables to achieve excellent results, notwithstanding the unavoidable approximations due to the  
20 various processings, that are based on the theoretic behavior of the involved mechanic parts.

#### Disclosure of Invention

25 Object of the present invention is to provide an apparatus for the dimensional and geometrical checking of pins rotating in the course of the machining in a machine tool, for example for the in-process checking, in a grinding machine, of crankpins rotating with an orbital motion, that  
30 guarantee the same standards of performance, in terms of accuracy and reliability, as those of the apparatuses according to the above-mentioned international patent applications and enables a simpler checking of the roundness characteristics of the pins.

35 This problem is solved by a checking apparatus of the hereinbefore mentioned type, wherein the coupling mechanism further includes constraining elements adapted for enabling

substantially translation displacements of the Vee-shaped device with respect to the stationary support element.

The support element according to the invention enables the Vee-shaped reference device and the measuring device to  
5 accomplish substantially plain translation displacements in the plane perpendicular to the axis of rotation. In other words, as shown in simplified form in figures 2a and 2b, the angular arrangement of the measurement direction **D** along which feeler **T** translates does not vary when the  
10 arrangement of the various parts forming the support device vary.

An advantage that the present invention provides is that of setting beforehand and regardless of the mutual position between support element and piece to be checked the angular  
15 arrangement of the contact direction of the feeler on the surface of the piece to be checked. In this way, should there be the need, for example, to utilize the apparatus for roundness checkings, at least part of the processings of the detected values - required for the checkings carried  
20 out by the known apparatuses - are not necessary, and this enables, among other things, to minimize the approximations in the calculations and make the checking operations more immediate and reliable.

#### 25 Brief Description of the Drawings

A preferred embodiment of the invention is now described in more detail with reference to the enclosed sheets of drawings, given by way of non-limiting example, wherein:

30 figures 1a and 1b show, in simplified form, the arrangement of a known apparatus under two different operating conditions;

figures 2a and 2b show, in simplified form, the arrangement of an apparatus according to the invention  
35 under the two different operating conditions shown in figures 1a and 1b;

- 5 -

figure 3 is a side view of a measuring apparatus according to a preferred embodiment of the invention, mounted on the grinding-wheel slide of a crankshaft grinding machine, shown in working conditions in the course of the checking of a crankpin while it is being machined;

figure 4 is a partly cross-sectional view of the measuring system of the apparatus according to a first embodiment;

figure 5 is a partly cross-sectional view of the measuring system of the apparatus according to a different embodiment;

figure 6 is a side view of a measuring apparatus according to a different embodiment of the invention, mounted on the grinding-wheel slide of a crankshaft grinding machine, shown in working conditions in the course of the checking of a crankpin while it is being machined;

figure 7 is a side view of the measuring apparatus of figure 6, shown in a rest condition;

figure 8 is a side view of a measuring apparatus, mounted on the grinding-wheel slide of a crankshaft grinding machine, according to a third embodiment of the invention;

figure 9, is a partly cross sectioned side view of a measuring apparatus according to a fourth embodiment of the invention, mounted on the grinding-wheel slide of a crankshaft grinding machine; and

figure 10 is a cross-sectional view of a particular of the apparatus of figure 9, along the line X-X of figure 9.

### Best Mode for Carrying Out the Invention

With reference to figure 3, the grinding-wheel slide 1 of a computer numerical control ("CNC") grinding machine for grinding a crankshaft supports a spindle 2 that defines the axis of rotation 3 of the grinding wheel 4. The grinding-wheel slide 1 carries a support device with a stationary support element 5 and a coupling mechanism including

- 6 -

coupling and constraining elements. More specifically, the support element 5 supports, by means of a rotation pin 6, a first rotating coupling element 9. Pin 6 defines a first axis of rotation 7 parallel to the axis of rotation 3 of grinding wheel 4 and to the axis of rotation 8 of the crankshaft to be checked. In turn, coupling element 9, by means of a second rotation pin 10, defining a second axis of rotation 11 parallel to axes 3 and 8, supports a second rotating coupling element 12. At the free end of the second coupling element 12 there is coupled, by means of a third rotation pin 13 defining a third axis of rotation 14 parallel to axes 3 and 8, a guide casing 15 wherein there can axially translate a transmission rod 16 carrying a feeler 17 for contacting the surface of crankpin 18 to be checked. The displacements of rod 16 are detected by a measuring device, as hereinafter disclosed. At the lower end of the guide casing 15 there is coupled a support block 19 that supports a Vee-shaped reference device 20, with rest and reference surfaces for engaging the surface of crankpin 18 to be checked. Feeler 17 and transmission rod 16 are movable substantially along a measurement direction that coincides with the bisecting line of the Vee-shaped reference device 20, or is slightly angular with respect to it, but in any case crosses the Vee-shaped device 20 between the associated rest and reference surfaces. The guide casing 15 is rigidly coupled (angularly adjustable in a known way that is not shown in detail in the figures) to a connecting rigid strip 30, also hinged on the rotation pin 13, and coupled, by means of a further pin 31, to an elongate element or rod 32. A linking element in the shape of an "L" or square 33 is hinged on pin 10, and, at a first end, by means of a pin 34, to rod 32. Another elongate element or rod 35 is hinged on the other end of the square 33 (by means of a pin 36) and on support element 5 (by means of a pin 37). A crankshaft 22 to be checked is positioned on the worktable 23, between centers, not shown, that define the

- 7 -

axis of rotation 8, coincident with the main geometrical axis of crankshaft 22. Consequently, crankpin 18 performs an orbital motion about axis 8. Even though crankpin 18 eccentrically rotates about axis 8, by describing a circular trajectory, the trajectory of the pin relative to the grinding-wheel slide 1 in the course of the machining can be represented, substantially, by the arc shown with a dashed line and identified by reference 25. As a consequence, the reference device 20, resting on crankpin 18, describes a similar trajectory, with a reciprocating motion from up to down and vice versa and at a frequency equal to that of the orbital motion of crankpin 18 (some tens of revolutions per minute). This is due to the fact that the checking apparatus is carried by the grinding-wheel slide 1 that, in modern numerical control grinding machines, machines the crankpins while they rotate in an orbital motion, by "tracking" the pins so as to keep the grinding-wheel in contact with the surface to be ground. Obviously, a feed motion for the stock removal is added to the transversal "tracking" motion. Thus, it is understood that the displacements of the elements forming the checking apparatus involve relatively small forces of inertia, to the advantage of the metrological performance, limited wear and reliability of the apparatus.

A control device, schematically shown in figure 3, includes a double-acting cylinder 28, for example of the hydraulic type. Cylinder 28 is supported by grinding-wheel slide 1 (in a known way, not shown in the figure) and comprises a rod 29, coupled to the piston of cylinder 28, carrying a cap 27 at its free end. A transmission arm 24 is rigidly and angularly coupled to the coupling element 9 and carries a positive stop element with an idle wheel 21. When cylinder 28 is activated for displacing the piston and the rod 29 to the right (with reference to figure 3), cap 27 contacts idle wheel 21 and makes the apparatus displace to a rest position according to which reference device 20 is

- 8 -

arranged above the geometric axis 8 and the upper position of crankpin 18.

The retraction of the checking apparatus to the rest position is normally controlled by the grinding machine numerical control when, on the ground of the measuring  
5 signal of the checking apparatus, it is detected that crankpin 18 has reached the required (diametral) dimension. Thereafter, the machining of other parts of the crankshaft takes place, or - in the event the machining of the  
10 crankshaft has been completed - the piece is unloaded, manually or automatically, and a new piece is loaded on worktable 23.

When a new crankpin has to be machined, it is brought in front of grinding wheel 4, usually by displacing worktable  
15 23 (in the case of a grinding machine with a single grinding wheel), and the apparatus displaces to the checking condition. This occurs by controlling, by means of the grinding machine numerical control, cylinder 28 so that rod 29 is retracted.

Thus, cap 27 disengages from idle wheel 21 and, through rotations of the coupling elements 9, 12 and the guide casing 15, due to the specific weight of the component parts of the checking apparatus, reference device 20  
20 approaches, by performing a trajectory with a mainly vertical component, crankpin 18, that in the meanwhile moves according to its orbital trajectory 25. Once the correct cooperation between crankpin 18 and reference device 20 is reached, this cooperation is maintained in the course of the checking phase by virtue of the displacements  
25 of the coupling elements 9, 12 and the guide casing 15 caused by the force of gravity and by the thrust of crankpin 18, the latter opposing the force of gravity of the component parts of the checking apparatus.  
30

It should be realized that the mechanism for coupling the  
35 measuring device to the support element 5 that includes, in addition to the first 9 and second 12 coupling elements, constraining elements including corresponding rods 35 and

- 9 -

32, the linking element 33 and the connecting strip 30, defines two parallelogram structures. These parallelogram structures that, as previously described, define axes of rotation parallel to the axes of rotation 3 and 8 of grinding wheel 4 and of crankshaft 22 to be checked, enable substantially plain translation displacements of the guide casing 15 and of the reference device 20 fixed to it, in other words enable to keep the angular arrangement of the direction of measurement along which feeler 17 displaces unchanged, regardless of the configuration taken by the various component parts of the coupling mechanism.

This facilitates, among other things, the checking of the roundness characteristics of the orbiting pin, because, as the angular arrangement of the contact direction of the feeler on the surface of the pin is known and constant (as shown in the sketches of figures 2a and 2b), the values detected by means of the measuring device need not undergo the associated compensations mentioned in the first part of the present description. In substance, the detected values do not depend on the reciprocal position between support element 5 and checked crankshaft 22 and on the characteristics and consequent configurations taken on by the support device carrying the measuring device.

Figure 4 shows some details of a possible embodiment of a device, or measuring head, 39 utilized in the apparatus according to the invention. The axial displacements of transmission rod 16 with respect to a reference position are detected by means of a measurement transducer fixed to casing 15, for example a transducer 41 of the LVDT or HBT known type with fixed windings 44 and a ferromagnetic core 43 coupled to a shaft 42 integral with transmission rod 16. The axial displacement of the transmission rod 16 is guided by two bushings 45, arranged between casing 15 and rod 16 and a compression spring 49 urges rod 16 and feeler 17 towards the surface of pin 18 to be checked or, in the absence of the pin, towards a rest position of feeler 17 defined by abutment surfaces not shown in the figures. A

- 10 -

metal bellows 46, that is stiff with respect to torsional forces and has its ends fixed to rod 16 and to casing 15 or a portion of block 19 integral to it, respectively, accomplishes the dual function of preventing rod 16 from rotating with respect to casing 15 (thus preventing feeler 17 from taking improper positions) and sealing the lower end of casing 15.

The support block 19 is secured to guide casing 15 by means of pairs of screws 47 passing through slots 48 and supports the reference device 20, consisting of two elements 38 with sloping surfaces, where to there are secured two bar shaped feelers 40. The rest position of feeler 17 can be adjusted by means of the screws 47 and slots 48.

The transducer 41 of measuring head 39 is connected to a processing and display device 51, in turn connected to the grinding machine numerical control 50 (both schematically shown in figure 3).

Figure 5 shows a device, or measuring head, 39' that differs with respect to head 39 insofar as the asymmetric arrangement of the Vee-shaped reference device 20' is concerned, the latter being arranged in such a way that the direction of measurement along which feeler 17 translates is angularly sloping with respect to the bisecting line of the Vee. In the example shown in figure 5, the amplitude of angles  $\alpha 1$  and  $\alpha 2$  is  $47^\circ$  and  $33^\circ$ , respectively. The use of the asymmetric Vee 20' is particularly advantageous for carrying out roundness checkings by means of an apparatus according to the present invention, in that it increases the apparatus sensitivity thereby enabling the checking of cylindrical surfaces with lobed cross-sections in a broad range of orders.

Figures 6 to 9 show, in a particularly simplified form, different possible embodiments of an apparatus according to the present invention.

More specifically, the apparatus according to figures 6 and 7 differs from the one shown in figure 3 in that it includes a different linking element achieved by means of a

- 11 -

plate 33' on which there are hinged coupling elements 9 and 12 and rods 32 and 35. With respect to the embodiment shown in figure 3, the second coupling element 12 is coupled to plate 33' by means of an additional rotation pin 10' in a stationary position with respect to pin 10.

An additional feature is present in the embodiment of figures 6 and 7 with respect to figure 3, i.e. an adjusting device with a plate 60 coupled to pin 6, pivotable about the first axis of rotation 7, and carrying pin 37' to which rod 35 is pivotably coupled.

The angular position of the adjusting plate 60 with respect to the support element 5 is fixed during the checking condition of the apparatus, thus fixing a side of one of the parallelogram structures, and consequently determining the angular arrangement of the direction of measurement along which feeler 17 displaces, as hereinbefore explained with reference to figure 3. The angular position of the adjusting plate 60 can be changed by means of known mechanical devices (not shown in the drawings) causing pivoting movements of plate 60 about axis 7, in order to change the above-mentioned angular arrangement of the direction of measurement along which feeler 17 displaces. The adjusting plate 60 can then be fixed in the new, modified position (by means of known mechanical means, not shown in the drawings), in order to perform new checking operations. This feature increases the flexibility of use of the apparatus, allowing easy and quick adjustments to obtain better performances in applications having different features as far as dimensions and/or arrangement of machine components are concerned. Moreover the angular position of adjusting plate 60 can be changed and then fixed (e.g. by automatic means) also while moving from the checking condition to the rest position (and vice-versa), in order to guarantee a safer position of the measuring head 39, far from the grinding wheel 4 and other moving machine parts, while the apparatus is in the inoperative condition shown in figure 7.

- 12 -

The adjusting plate 60 can be employed in the embodiment of figure 3, too.

In the apparatus shown in figure 8, one of the two parallelogram structures is replaced by a linear guide or slide - shown in simplified form in the figure and identified by reference number 70 - by means of which a linking element 33'' is coupled, in a slidably constrained way, to the support element 5. The coupling element or arm 12 and rod 32 are coupled to the linking element 33'' by means of the pins 10' and 34, respectively. An adjusting plate similar to the one (60) of figure 6 and 7 can be connected to plate 33', pivotable about pin 10' and carrying pin 34.

The support devices of the embodiments shown in figures 6, 7 and 8 have coupling mechanisms that include, as the support device shown in figure 3, coupling elements and constraining elements that enable reference Vee 20 (or 20') to approach to and displace away from pin 18 to be checked - and to "track" pin 18 in its orbital trajectory - by performing translation displacements according to which the direction of measurement defined by the displacements of feeler 17 and of transmission rod 16 remains substantially parallel to itself.

The embodiments shown in figures 3 and 6 to 8 are illustrated as an example only, while other embodiments fall within the scope of the invention. For example, the coupling mechanism of the support device can include two support sections coupled "in series" - like the parallelogram structures of figures 3, 6 and 7, or the slide and the parallelogram structure of figure 8 - and each of the two sections defines constraints that allow just plain reciprocal translation displacements among the coupled parts. Besides the parallelogram type structures and slides, there are other known devices that have the above mentioned features, for example the coupling mechanism schematically shown in the embodiment of figures 9 and 10, where the two support sections include rotating

- 13 -

coupling elements 79 and 82 having parallelepipedon-shaped closed housings 74 and 75, respectively. More specifically, the first coupling element 79 is pivotably connected to the support element 5 by means of a stationary pin 76 engaging bearings in the housing 74 (not shown in the figures) and defining a first axis of rotation 77. A second pin 80 defining a second axis of rotation 81 cooperates with bearings in both housings 74 and 75 (figure 10, where, for the sake of simplicity, bearings are not shown), to allow mutual rotating movements between first and second coupling elements 79 and 82. At the free end of the second coupling element 82, there is coupled, by means of a third pin 83 and corresponding bearings in housing 75 defining a third axis of rotation 84, the guide casing 15 of measuring head 39 (or 39').

Constraining elements include a first, stationary, pulley 85 that is fixed to stationary pin 76, second and third pulleys 86 and 87 fixed to the second pin 80, and a fourth pulley 88 fixed to the third pin 83. The constraining elements also include first and second belts 89 and 90 (e.g. toothed belts) tightly coupled to the first (85) and second (86) pulleys and to the third (87) and fourth (88) pulleys, respectively. By virtue of the arrangement of the two support sections including housings, pulleys and belts as above specified, the angular arrangement of the direction of measurement along which feeler 17 displaces remains unchanged during movements of the coupling mechanism involving mutual rotation between elements 79 and 81. In fact, during pivotal movements of coupling element 79 about axis 77, the first belt 89 constrains the second pulley 86 to keep its angular arrangement about axis 81. The third pulley 87 is fixed to pin 80 like pulley 86, and consequently its angular arrangement about axis 81 remains unchanged, too. In the same way, the second belt 90 prevents fourth pulley 88 from rotating about axis 84. As a result, the angular arrangement of the third pin 83 - rigidly fixed to pulley 88 and carrying guide casing 15 -

- 14 -

about axis **84** does not change during pivotal movements of the coupling elements **79** and **82**, thus keeping the angular arrangement of the direction of measurement along which feeler **17** displaces, and enabling plain translation  
5 displacements of the head **39**.

A possible additional feature of the embodiment of figures 9 and 10 consists in an adjusting device including an adjustable coupling between the first stationary pulley **85** and the support element **5**, that employs per se known means  
10 that are not shown in the drawings. The adjustable coupling allows to modify and fix the angular arrangement of the pulley **85** about axis **77**, in order to perform adjustments of the coupling mechanism in the same way as hereinbefore described in connection with the adjusting plate **60** of  
15 figures 6 and 7.

The embodiment of figures 9 and 10 has some advantages with respect to the other previously described embodiments as far as the tightness is concerned. In fact, the substantially closed structure and the possibility of  
20 easily seal the openings with bearings of housings **74** and **75**, prevent dust and coolant from interfering with the proper operation of the apparatus.

Embodiments according to the present invention can also include coupling mechanisms, per se known, not clearly  
25 divisible in two sections having the above described features, that comprise coupling elements and constraining elements the combined displacements of which enable to constrain the mutually coupled parts to accomplish substantially plain translation displacements.

Other possible variants with respect to what has been herein described and illustrated can also regard the structure and the arrangement of the control device and/or the use of limiting devices with abutment surfaces, for  
30 example for limiting the reciprocal rotations among the various parts of the support device in the rest position.

Furthermore, it is also possible to foresee an additional guide element coupled to reference device **20**, and/or a

- 15 -

balance spring, achieved, for example, as disclosed in international patent application WO-A-9712724.

An apparatus according to the invention is particularly suitable for the in-process checking of crankpins in orbital motion, but can obviously be utilized for dimensional or shape checkings of pins in orbital motion before or after the machining, as well as for checkings (before, during or after the machining) of pins rotating about their symmetry axes.

10

- 16 -

CLAIMS

1. An apparatus for checking dimensional and geometrical features of a pin (18), rotating about a geometrical axis of rotation (8), with
- a Vee-shaped device (20;20') that defines rest and reference surfaces adapted for cooperating with the pin (18) to be checked,
  - a measuring device (39;39'), coupled to the Vee-shaped device (20;20') and including
    - a feeler (17) for contacting the surface of the pin to be checked and performing linear displacements along a measurement direction (D) laying between said rest and reference surfaces of the Vee-shaped device (20;20'), and
    - a support device for supporting the Vee-shaped device (20;20') and the measuring device (39; 39'), the support device including
      - a stationary support element (5), and
      - a coupling mechanism with coupling elements (9,12;79,82) coupled in a movable way to the stationary support element (5) and carrying the Vee-shaped device (20),
- characterized in that said coupling mechanism further includes constraining elements (30,32,33,35;33';33'',70;85-90) adapted for enabling substantially translation displacements of the Vee-shaped device (20;20') with respect to the stationary support element (5).
2. The apparatus according to claim 1, wherein said coupling elements (9,12;79,82) and constraining elements (30,32,33,35;33';33'',70;85-90) define two support sections coupled in series.
3. The apparatus according to claim 1 or claim 2, wherein at least some of said coupling elements (9,12;79,82) and constraining elements (30,32,33,35;33';33'',70;85-90) are

- 17 -

adapted to perform angular displacements about axes (7,11,14;77,81,84) parallel to said geometrical axis of rotation (8).

- 5 4. The apparatus according to claim 2, wherein said coupling elements (9,12) and constraining elements (30,32,33,35;33';33'',70) define a parallelogram structure with four axes of rotation parallel to said geometrical axis of rotation (8).

10

5. The apparatus according to claim 4, wherein said coupling elements (9,12) and constraining elements (30,32,33,35;33') define an additional parallelogram structure with four additional axes of rotation parallel to  
15 said geometrical axis of rotation (8).

6. The apparatus according to claim 5, wherein each of said support sections includes one of said parallelogram structure and additional parallelogram structure.

20

7. The apparatus according to claim 6, wherein each of said parallelogram structure and additional parallelogram structure includes a coupling element (9,12) and a constraining elongate element (35,32), said constraining  
25 elements further include a linking element (33;33') coupled in a rotating way to the free ends of said coupling elements (9,12) and constraining elongate elements (35,32).

8. The apparatus according to claim 7, wherein said  
30 coupling elements (9,12) are coupled to said linking element (33) in a rotating way about an identical axis of rotation (11).

9. The apparatus according to one of claims 2 to 4,  
35 wherein at least one of said sections includes a linear guide (70).

- 18 -

10. The apparatus according to claim 2, wherein the  
constraining elements include pulleys (85-88) and belts  
(89,90), each of said support sections including a rotating  
coupling element (79,82), a couple of said pulleys (85-  
5 86,87-88) and one of said belts (89,90).

11. The apparatus according to claim 10, wherein each of  
said support sections includes a substantially closed  
housing (74,75), said couple of pulleys (85-86,87-88) and  
10 belt (89,90) being arranged within the housing (74,75).

12. The apparatus according to claim 11, wherein one of  
said support sections include a first stationary pulley  
(85) coupled to the stationary support element (5), a  
15 second pulley (86) and a first belt (89) coupled to said  
first and second pulleys (85,86), the other of said support  
sections including a third pulley (87), a fourth pulley  
(88) and a second belt (90) coupled to said third and  
fourth pulleys (85,86), the Vee-shaped reference device  
20 (20;20') and the measuring device (39;39') being rigidly  
connected to the fourth pulley (88), the second (86) and  
the third (87) pulleys being mutually rigidly connected.

13. The apparatus according to one of the preceding  
25 claims, further including an adjusting device (60) coupled  
to at least one of said constraining elements  
(30,32,33,35;33';33'',70;85-90) for adjusting and fixing  
the angular arrangement of said measurement direction (D).

14. The apparatus according to claim 5, further including  
an adjusting device (60) coupled to one of said  
parallelogram structure and additional parallelogram  
structure for adjusting and fixing the angular arrangement  
of said measurement direction (D) by adjusting the mutual  
35 position of at least two of said axes of rotation and  
additional axes of rotation.

- 19 -

15. The apparatus according to claim 14, wherein said adjusting device (60) is coupled to the stationary support element (5) and to one of said parallelogram structure and additional parallelogram structure.

5

16. The apparatus according to one of the preceding claims, including a control device for controlling automatic displacements of the measuring device from a rest position to a checking condition and vice versa.

10

17. The apparatus according to one of the preceding claims, for the diameter and the roundness checking of a pin (18) orbiting about a geometric axis of rotation (3), in the course of the machining in a numerical control grinding machine with a worktable that defines said geometric axis and a grinding-wheel slide (1) carrying a grinding-wheel (4), wherein the stationary support element (5) is coupled to the grinding-wheel slide.

## INTERNATIONAL SEARCH REPORT

International Application No

PCT/EP 02/02022

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 B24B5/42 B24B49/04 G01B5/00

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 B24B G01B B23Q

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

## \* Special categories of cited documents:

\*A\* document defining the general state of the art which is not considered to be of particular relevance

\*E\* earlier document but published on or after the international filing date

\*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

\*O\* document referring to an oral disclosure, use, exhibition or other means

\*P\* document published prior to the international filing date but later than the priority date claimed

\*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

\*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

\*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

\*&amp;\* document member of the same patent family

Date of the actual completion of the international search
